RED
Red is a popular color choice in the deep sea and there is a reason for it. Light is made of photons that act as waves, which we see as color. These color waves scatter and become less frequent with water depth at different rates. The photons responsible for red waves scatter very quickly, and few make it to deeper water.
Animals that appear red in otherwise full light appear black in the deep because the photons responsible for red waves do not reach them. This means few red photons bounce off these red animals and into the eyes of other animals. Red animals stay better hidden making red pigment a great adaptation for deeper waters.
